About this Document

This document lists all valid ELFF and CPL substitutions for ELFF log formats, and some custom values for custom log formats.

Substitutions allow you to fetch information from the current transaction. This information can be optionally transformed, and then substituted into a character string or block of text.

Substitutions can occur in the following contexts:

- In exception pages, ICAP patience pages, and authentication forms; refer to the *SGOS Administration Guide* for details
- In the definition of substitution realms; refer to the *SGOS Administration Guide* for details
- In CPL `define string` statements, and inside most (but not all) `"..."` or `'...'` string literals
- In some Visual Policy Manager objects, such as **Event Log** and **Notify User**

The following is an example of a substitution:

```
$(user)
```

The general syntax for a substitution is:

```
"$(" field modifier* ")"
```

where:

- *field* is an ELFF field name or a supported CPL substitution. When a field supports both ELFF and CPL, the values are interchangeable; for example, `$(cs-ip)` and `$(proxy.address)` are equivalent. You can use either one in an ELFF format.
- *modifier* transforms the field name or substitution value specified in *field*. A substitution can contain zero or more modifiers after the field name. Modifiers are interpreted from left to right. For more information, see "Substitution Modifiers" on page 176.

Note: `$(request.x_header.<x-header-name>)` and `$(response.x_header.<x-header-name>)` are also valid substitutions.

Note: You can use `$$` as a CPL substitution that is replaced by `$`. If, for example, you are using jQuery to customize an exception page on the appliance, the jQuery `$` function such as `$('body')` will be reported as an error. This error occurs because the appliance interprets the jQuery `$` function as an invalid CPL substitution. To prevent the misinterpretation of the jQuery function, use `$$('body')` instead of `$('body')`.

For more information on ProxySG access logs, refer to the *SGOS Administration Guide*. For details on CPL, refer to the *Content Policy Language Reference*. Documentation is available at MySymantec: https://support.symantec.com/en_US/Documentation.1145522.2116810.html

Note: This document does not describe access log fields pertaining to features deprecated in SGOS 6.5.x and earlier (such as Surfcontrol, Websense, and IM proxies).

Tip: You can download the complete list of access log field names at <https://www.symantec.com/docs/DOC11251>.

Substitution Modifiers

Some substitutions can be altered by appending various modifiers.

In general, modifiers have the following syntax:

```
:modifier_name(arguments)
```

They are appended to the field name in the substitution expression as follows:

```
$(field_name:modifier(arguments))
```

Modifiers can also be chained together to produce the desired result, as follows:

```
$(field_name:first_modifier(arguments):second_modifier(arguments))
```

The following types of substitution modifiers are available:

- "Timestamp Modifiers" on the next page
- "String Modifiers " on page 179
- "Host Modifiers" on page 182

Timestamp Modifiers

Timestamp modifiers are restricted to working on specific substitution fields that represent timestamp functions, such as:

- `$(date)`
- `$(time)`
- `$(cookie_date)`
- `$(http_date)`

The timestamps produced by these substitutions can be altered by adding any of the following modifiers.

- `days.add`—Add or subtract days (24 hours). For example, `$(cookie_date:days.add(2))` yields a timestamp 48 hours into the future in cookie expiry time format.
- `hours.add`—Add or subtract hours. For example, `$(http_date:hours.add(-1))` yields a timestamp one hour into the past in HTTP 1.1 header format.
- `minutes.add`—Add or subtract minutes. For example, `$(cookie_time:minutes.add(15))` yields a timestamp 15 minutes into the future in cookie expiry time format.
- `next_date`—Skips forward zero or more seconds to the next date matching the specified pattern.

To evaluate `next_date()`, the current cycle must be determined.

A date pattern has the following syntax:

`[month] [day-of-month] [weekday] [HH:MM | HH: | :MM]`

- All of the components are optional, but at least one component must be present.
- A month is a month-name abbreviation from `jan` to `dec`.
- A day-of-month is either a number from 1-31, or it is the string `last`.
- A weekday is a weekday abbreviation from `mon` to `sun`.
- `HH:MM` is expressed in 24-hour time, from 00:00 to 23:59.

For example, the following are all synonyms that advance zero or more seconds to the next occurrence of January 00:00:00:frame's search

- `:next_date(jan)`
- `:next_date(jan 1)`
- `:next_date(jan 1 00:00)`

For example, you can use these modifiers to construct a `Set-Cookie` header with an explicit expiry time. To set a cookie that expires at midnight:

```
<proxy>
  action.setcookie(yes)
    define action setcookie
      set(response.header.Set-Cookie,
        "myname=myvalue; expires=$(cookie_date:next_date(00:00))")
    end
```

Examples

Expires at 2 a.m.

```
$(cookie_date:next_date(2:00))
```

Expires at 2 a.m. tomorrow

```
$(cookie_date:next_date(00:00):next_date(2:00))
```

Note: The first `next_date` is to the next midnight, ensuring that if the time is between midnight and 2 am, the 2 am generated is not today's.

Expires at 2 a.m. the day after tomorrow

```
$(cookie_date:next_date(00:00):add.days(1):next_date(2:00))
```

Expires at 2 am Monday morning

```
$(cookie_date:next_date(Mon 2:00))
```

Expires at 10 pm the last day of the month

```
$(cookie_date:next_date( last 22:00 ))
```

Expires at 2am the third Tuesday of the month

Note: The third Tuesday of the month must be between the 15th and 21st.

```
$(cookie_date:next_date( 15 Tue 2:00))
```

This advances zero or more seconds to the 15th of the month, and then advances zero or more seconds to Tuesday, then advances 0 or more seconds to 2 am.

String Modifiers

These substitution modifiers can be applied to any field.

Modifier	What It Does	Example of Usage
<code>binary_address</code>	Converts a dotted IP address into 4 bytes, where one byte represents an octet.	Convert the client address into a four byte representation: <code>\$(client.address:binary_address)</code> 10.11.12.13 is converted to 0x0A0B0C0D.
<code>concat(string)</code>	Concatenates the argument to the base string produced by the field it operates on. The result is a literal string that may need to be enclosed in quotes, depending on the context.	Concatenate the requested URL with the authenticated user: <code>log_message("\$ (url:concat(?\$(user)))")</code> The log shows the URL concatenated with the username: <code>http://www.example.com/index.html?mark</code>
<code>escape_ldap_filter</code>	Specifies that a policy substitution value should be escaped using the LDAP search filter syntax as specified in RFC 2254 . This modifier does not take arguments.	Escape the user value when the search filter is <code>(cn=\$(user:escape_ldap_filter))</code> and the username is <code>domain\user</code> . The escaped value is: <code>(cn=domain\5cuser)</code> The byte value of <code>\</code> is <code>5c</code> , so it is escaped as <code>\5c</code> .
<code>encode_base64</code> and <code>decode_base64</code>	Encodes and decodes URLs. These modifiers do not take arguments.	Encode the concatenated URL to base64 in the log: <code>log_message("\$ (url:concat(?\$(user)):encode_base64)"</code> Decode from base64: <code>\$(url.query:rewrite((.*);(.*) ,\$(1)):decode_base64)</code> The log shows the base64-encoded URL concatenated with username: <code>aHR0cDovL3d3dy5leGFtcGxlMnVbS9pbmRleC5odG1sP21hcms=</code>

Modifier	What It Does	Example of Usage
hmac	<p>Replaces the string field with a SHA-256 digital signature for that string. This uses the encrypted key stored in the command:</p> <pre> #(config)policy hmac encrypted-key </pre> <p>The digital signature is base-64 encoded.</p>	<p>This modifier has the syntax <code>field:hmac</code> where the field is the name of a policy substitution text variable plus any text substitution functions to rewrite. Consider the example:</p> <pre>exception(content_filter_denied, "\${url:hmac}")</pre>
if_null	<p>Useful for checking whether a variable has been defined and if one is not defined, a default value can be assigned to the variable.</p>	<p>Consider the example:</p> <pre>S1:if_null(S2)</pre> <p>If the left argument S1 is a non-empty string, return S1. Otherwise, S1 is an empty string, return string S2.</p>
\$(iterator)	<p>When used in <code>iterate()</code>, this field returns the current string value being iterated over. Otherwise, this returns an empty string.</p>	<p>Write policy to sign all cookies:</p> <pre> define action sign_all iterate(response.header.Set-Cookie) iterator.append("\${iterator}:rewrite([[^=]*)= \ ([^;]*) (.*),BCSIG_\${1}=\${2:hmac}\${3}))") end end </pre>
rewrite(regex, substitution)	<p>Rewrites the text field prefix passed in based on the regex and replacement string parameters.</p>	<p>The syntax is:</p> <pre>field:rewrite(regex_pattern, replacement_string)</pre> <p>To log the signature for a URL to the event log:</p> <pre>exception(content_filter_denied, "Protocol for URL is \ \${url:rewrite([[^:]*)(.*),\$(1)}")</pre>

Symantec Corporation - SGOS 6.x and 7.x

Modifier	What It Does	Example of Usage
<code>\$(session.username:encode_hex)</code>	Converts an ASCII variable string into a hex representation.	<p>Consider the example:</p> <p><code>*#911#</code> is converted in hex to <code>2A23393131123</code>.</p> <p>Use this modifier to insert a separator between each converted byte; alternatively, use <code>0x\$(session.username:encode_hex(0x))</code>.</p> <p>With <code>\$(session.username:encode_hex())</code>, <code>*#911#</code> becomes <code>2A 23 39 31 31 23</code>.</p> <p>With <code>0x\$(session.username:encode_hex(0x))</code>, <code>*#911#</code> becomes <code>0x2A 0x23 0x39 0x31 0x31 0x23</code>.</p>
<code>url_escape</code>	<p>Escapes special characters in the URL string as <code>%xx</code>.</p> <p>A special character is defined as any character that cannot be passed in its original form in a URL, in an access log field, or in an HTML attribute value, etc.</p> <p>The non-special characters are: A-Z, a-z, 0-9, <code>_</code>, <code>-</code>, <code>.</code>, and <code>%</code>. Use <code>url_escape_all</code> to consider <code>%</code> to be a special character.</p>	<p>Consider the example:</p> <p>The username is <code>us%;1</code></p> <p><code>\$(user:url_escape)</code> displays <code>us%r%3b1</code></p> <p>The <code>;</code> is escaped as <code>%3b</code>.</p>
<code>url_escape_all</code>	Escapes all special characters in the URL, including <code>%</code> .	<p>Consider the example:</p> <p>The username is <code>us%;1</code></p> <p><code>\$(user:url_escape_all)</code> displays <code>us%25r%3b1</code></p> <p>The <code>%</code> is escaped as <code>%25</code> and the <code>;</code> is escaped as <code>%3b</code>.</p>

Host Modifiers

This substitution modifier can be applied to the `$(url.host)` field.

- `label(n)`—This modifier extracts the *n*th label from a host. Labels are numbered from 1, with label 1 being the top level domain (such as `.com` or `.net`).

For example, given the URL “`http://publications.my_company.com`”

- `$(url.host:label(1))` yields “`com`”
- `$(url.host:label(3))` yields “`publications`”
